Abstract
The main purpose of this research is to recognize the relationship between Operating profit and capital productivity indexes on the basis of financial statements yearly published by the North Industrial Wood Firm. The type of this research method is applied for the purpose and it is a case study for the procedure, so choosing an economical unit named the North Industrial Wood Firm as a population evaluates and recognizes the relationships between independent variables and dependent variables. In this research, the dependent variable is operating profit and independent variables are capital productivity indexes. In this research, for data analysis, descriptive statistics (the mean and standard deviation) and inferential statistics (correlation test) were used. Also by using the survey of documents and degrees of the North Industrial Wood Firm in a period of 11 years (1995-2006), necessary information was put into special tables and then analyzed statistically. Findings of the research showed that there is a meaningful correlation at the level of %5 between capital productivity indexes and operating profit.

Keywords
Operating profit, Capital productivity, Financial information, Economical unit

I. Introduction
Productivity is somehow a know language and researches, articles, books, seminar and various conferences in different industries that is attracts to itself, meanwhile it is not know. In a brief study of the process in different countries, particularly in far Asian countries we notice that the main basis of fast economical development is the productivity. Several activities are there that large industries can not do them because of economical or technical reasons. Small industries do them. Small and middle industries do an important part in economical progress and industrial development of a country. Productivity always relates an output to one or some bases (factors) that are used in production. One concept 'Unique', 'Super' or 'Fixed' in productivity measurement does-not exist [1]. According to productivity definition, if the factors of output production are used (man power, capital, raw materials, field) best, surely productivity will enhance. Among these production factors, labor is one of the most important entrance sources. Therefore productivity is the most important factor of success in an organization and even it is called the productivity in several organizations generally. Labor and capital are considered as two helping factors and in fact two basic factors of production. Therefore, as easily we talk about the labor productivity, we can talk about capital productivity as well. In fact, the capital productivity is the most important measuring ratio of productivity after the labor productivity and it is a pretty suitable information for making decisions of management. Total productivity is a ratio totally that considers the common and the same time effect of all bases such as labor, material, mechanical tools, capital, energy and so on in relation to the rate and value of production [2].

Three different aspects of evaluation of a firm’s function are:
1. Stock Market Returns
2. Productivity Measures
3. Financial Information

II. Materials and Method
The method of study is functional in aspect of purpose and it is a case study in aspect of method, that with election of an economical unit named the North Industrial Wood Firm as a population evaluates and recognizes the relationships between independent variables and dependent variables. In this research, the dependent variable is operating profit and independent variables are capital productivity indexes. In this research, for data analysis, descriptive statistics (the mean and standard deviation) and inferential statistics (correlation test) were used. Also by using the survey of documents and degrees of the North Industrial Wood Firm in a period of 11 years (1995-2006), necessary information was put into special tables and then analyzed statistically. Findings of the research showed that there is a meaningful correlation at the level of %5 between capital productivity indexes and operating profit.

According to a capitalist, productivity is the concept of "Capital Return". Therefore, profit is considered as an output. Productivity is mainly the guarantee profit at a high level for a firm whereas a low productivity leads to reduction of profit relation (level). Generally, decrease in profitability, productivity or price covering leads to reduction of profit. Productivity decrease is the sign of more analytical necessity and improving actions. The profit of a firm also depends on productivity to a great extent for a long time. In the following equation, the relationship between profitability and productivity is shown:

\[ \text{Profitability} = \text{Physical Productivity Process} \times \text{Price Covering} \]

So a firm has to emphasize on two cases of productivity and price improvement (recovery) to get much profit as possible as it’s shown in Fig.2 [13].

The final goal of every productive or industrial activity is more profitability that involves the correct use of sources and facilities (productive factors) and cost reduction and in other words productivity increase. Profitability or getting advantage means the relation of profit with used capital. The main purpose of this research is to recognize the relationship between Operating profit and capital productivity indexes on the basis of financial statements yearly published by the North Industrial Wood Firm.

Fig.1: Different Aspects of Evaluation of a Firm’s Function
Fig.2: Strategy for Profitability
The economical unit named the north industrial wood company as a society the relation between dependent and independent variables is evaluated. In this study, the dependent variable, operating profit and independent variables are capital productivity indexes (capital productivity, total output to fixed assets, capital intensity, total output to operating capital, operating capital circulation, fixed assets circulation and total assets circulation).

In this study, two following methods were used for collecting information:

1. Library study, to collect resources and to know about the researches done in this field, is one of the most important methods of gathering information in scientific study.
2. Field study, in which the present documents and evidences of the firm, the statistics and information center (the computer center) of the firm with reference to them, the necessary information was collected for analyzing hypotheses.

The computer software used in calculating the indexes related to the researching subject and estimating the relevant regressions are Excel 2007 and SPSS. All used variables in aspect of statistics, contains the normal distribution with average and standard deviation indicated in the “Table 1”. According to Kolmogorov-Smirnov Test, there isn't any adequate reason for rejecting the hypothesis of being normal of the data:

H0: Data are normal
H1: Data are not normal

While Sig <0/05 is, H0 hypothesis (being normal of data) is rejected. Otherwise there's not any adequate reason for rejecting H0 hypothesis. In the above table, in all cases Sig is larger than 0/05.

Sig Test of the typical correlation by t test student is done while in this test, data are normal and ρ is the parameter of correlation coefficient and r is a typical correlation coefficient that is taken from the relation:

\[
r = \frac{\sum_{i=1}^{n} (X_i - \bar{X})(Y_i - \bar{Y})}{\sqrt{\sum_{i=1}^{n} (X_i - \bar{X})^2} \times \sqrt{\sum_{i=1}^{n} (Y_i - \bar{Y})^2}}
\]

that is an estimation from ρ so in the hypothesis.

\[
H_0: \rho = 0 \quad \Rightarrow \quad t = \frac{r - \rho}{\sqrt{\frac{1-r^2}{n-2}}} \quad \sim \quad t_{n-2, \gamma}
\]

\[
H_1: \rho \neq 0 \quad \Rightarrow \quad t > t_{n-2, \gamma} \quad \Rightarrow \quad \text{Reject } H_0
\]

H0 is rejected when Sig <0/05 is while there would be a meaningful correlation between two variables at the level of 0/05. Also by the multi-correlation coefficient R (which is) taken from regressive models (with SPSS software), the notice to the following category is of a high important:

If R >0/70 in this multi correlation is strong (the more it's nearer to number one, the stronger correlation it shows) and if 0/20 < R <0/70 in this multi correlation is weak and if R<0/20 multi correlation isn't there. So if we want to get a regressive model in concern with different styles of regressive modeling in the field of economics measuring, will use the method of Stepwise (the compound model of back ward and forward) in order to get the best regressive model. In the method, the variables which contain a more suitable correlation with the dependent variable has more chance to enter the model, otherwise they get out of the model. In this way, regressive variables are shown in “Table 2”.

The main Hypothesis in this research is:

There is a meaningful relationship between capital productivity indexes and operating profit.

Secondary hypotheses in this study are as follows:

1-1) There is a meaningful relationship between capital productivity and operating profit.
1-2) There is a meaningful relationship between total output to fixed assets and operating profit.
1-3) There is a meaningful relationship between capital accumulation and operating profit.
1-4) There is meaningful relationship between total output of operating capital and operating profit.
1-5) There is a meaningful relationship between operating capital circulation and operating profit.
1-6) There is a meaningful relationship between fixed assets circulation and operating profit.
1-7) There is a meaningful relationship between total assets circulation and operating profit.

III. Discussion

There are several important profit measures in common use. Note that the words earnings, profit and income are used as substitutes in some of these terms (also depending on US or UK usage), thus inflating the number of profit measures. Gross profit equals sales revenue minus cost of goods sold (COGS), thus removing only the part of expenses that can be traced directly to the production or purchase of the goods. Earnings Before Interest, Taxes, Depreciation, and Amortization (EBITDA) equals sales revenue minus cost of goods sold and all expenses except for interest, amortization, depreciation and taxes. It measures the cash earnings that can be used to pay interest and repay the principal. Since interest is paid before income tax is calculated, the debt holder can ignore taxes. Operating profit or Earnings Before Interest and Taxes (EBIT) equals sales revenue minus cost of goods sold and all expenses except for interest and taxes. This is the surplus generated by operations. It is also known as Operating Profit Before Interest and Taxes (OPBIT) or simply Profit Before Interest and Taxes (PBIT) [4]. Earnings Before Tax (EBT) or Net Profit Before Tax equals sales revenue minus cost of goods sold and all expenses except for taxes. It is also known as pre-tax book income (PTBI), net operating income before taxes or simply pre-tax income. Earnings After Tax or Net Profit After Tax equals sales revenue after deducting all expenses, including taxes (unless some distinction about the treatment of extraordinary expenses is made). In the US, the term Net Income is commonly used. Income before extraordinary expenses represents the same but before adjusting for extraordinary items. Earnings After Tax (or Net Profit After Tax) minus payable dividends becomes Retained Earnings. To accountants, Economic Profit, or EP, is a single-period metric to determine the value created by a company in one period - usually a year. It is Earnings After Tax less the Equity Charge, a risk-weighted cost of capital. This is almost identical to the economists’ definition of economic profit. There are analysts who see benefit in making adjustments to economic profit such as eliminating the effect of amortized goodwill or capitalizing expenditure on brand advertising to show its value over multiple accounting periods. The underlying concept was first introduced by Schmalenbach, but the commercial application of the concept of adjusted economic profit was by Stern Stewart & Co. which has trade-marked their adjusted
economic profit as Economic Value Added (EVA). Economists define also the following types of profit:

- Abnormal profit (or Supernormal profit)
- Subnormal profit
- Monopoly profit (or Super profit)

Optimum Profit is a theoretical measure and denotes the "right" level of profit a business can achieve. In business, this Fig. takes account of marketing strategy, market position, and other methods of increasing returns above the competitive rate. Accounting profits should include economic profits, which are also called economic rents. For instance, a monopoly can have very high economic profits, and those profits might include a rent on some natural resource that firm owns, whereby that resource cannot be easily duplicated by other firms [14].

Today, productivity is considered as a thoughtful status and an intellectual meaning of working. The initial concepts are simple. The problem in the productivity discussion is the lack of a definite and certain procedure (method) for productivity. Of necessities for making intellectual of productivity is to present definitions on productivity and its evaluation indexes. Productivity is the relation between products or produced services and used resources in production. Productivity is a real concept that is a relation degree between a physical output and a physical input. Productivity is an evaluation of an institute's distribution and production process; for instances, one's goods quality and produced services and used resources or else [3]. Productivity involves effectiveness and efficiency and also a total of results and products with(at) the highest level of function.

Robbins defines productivity like this: "the quantity or proportion of products or the main services are presented by organization." [11]. Kawan Lie defines productivity as, "the measurable relation between the proportion of products and the proportion of used factors/resources needed for making the product." [6]. Increase in productivity also can affect the society in a wide way with producing earnings improvement and life standards growth. The real meaning of productivity is this: more production with the same attempt of manpower. Productivity increase is a key for competition in domestic, national and international levels [10].

Peter Druker writes anywhere, "the explosion of productivity has been the most important social event during the last hundred years, that is unique during history." Druker, with referring to South Korea (1955) points out that a week and underdeveloped country has developed during twenty years by paying attention to productivity issue and constant and intelligent attempt until the country has developed during twenty years by paying attention to productivity issue and constant and intelligent attempt until it has become a developed country [5]. As shown in "Table 3", many definitions of productivity that are indicated by experts and researchers in this field, confirm the reality that despite of vast studies and (vast) surveys done in this field, there's still no agreement on the productivity concept and about basic concepts [13]. Johnson and banker (1994) by using the airline industry process as their experimental function, got a result that there is an extreme positive correlation between profitability and productivity.

Sjøgren, Marton, Holmen(2002) in the process of research of airline industry got result that there is a direct and positive correlation between stock market returns and productivity indexes and there is a negative correlation between productivity indexes and operational expenses. Kitaeva(2002) in a research called, "relationship between productivity measures and financial information in the airline industry" studied 35 airlines in 25 countries in a period of 1991 to 1999. He also received a result that there is a negative correlation between operating expenses and efficiency measures [7]. To measure productivity in industrial units, with studied done, among numerous indexes related with productivity in industries, the most effective and important ones in economical and financial function of elected industrial units and the concepts of these indexes and how to measure them and their analysis are described in "Tables 3".

The more the independent equations are, the clearer of the institute's situation is indicated. Productivity is a measure of the efficiency of production. Productivity is a ratio of what is produced to what is required to produce it. Usually this ratio is in the form of an average, expressing the total output divided by the total input. Productivity is a measure of output from a production process, per unit of input. At the national level, productivity growth raises living standards because more real income improves people's ability to purchase goods and services, enjoy leisure, improve housing and education and contribute to social and environmental programs. Productivity growth is important to the firm because it means that the firm can meet its (perhaps growing) obligations to customers, suppliers, workers, shareholders, and governments (taxes and regulation), and still remain competitive or even improve its competitiveness in the market place.

IV. Conclusion
In a socialist economy, capital productivity characterizes the efficiency with which fixed capital stock is used. It is commonly employed in economic analysis and in the formulation of production plans and plans for capital expenditures, both for the national economy as a whole and for individual sectors, production associations, and enterprises. Data on the gross social product and on national income (from productive activities) are used in calculating capital productivity for the national economy as a whole; for calculating the productivity of individual sectors, data on gross (commodity) or net output are used. In sectors where the output is homogeneous (petroleum, coal, cement), physical units are sometimes used in the calculations. Capital productivity is calculated on the basis of the balance valuation of the fixed production assets (depreciation costs included), using either the average value over the year or the value as of the end of the year. Capital productivity is the reciprocal of the capital-output ratio.

By referring to "Table 4", in hypotheses 1-1, 1-2, 1-3 and 1-6 because of being lower than 5% Sig, there is a meaningful relationship between operating profit and indexes through these hypotheses. But in hypotheses 1-4, 1-5 and 1-7 there's no meaningful correlation between operating profit and indexes through these hypotheses (Sig >0.05) at the level of 5%.

In the survey of the above table, R is 0.997 that it indicates a very strong correlation. It means that the second hypothesis is confirmed generally.

Also this hypothesis's regressive model is:

$$Y = -10423609212.3 + 12122307253.281X_1 + 125.566X_1$$

With notice to the importance of the study subject and considering the gained results from this study, the following suggestions are presented:

1. It is suggested that the higher and middle degree managers of the north industrial wood company build a unit to survey and control the productivity indexes, by which they make better decisions.

2. Notice to the study's results showed that among labor productivity indexes, "labor productivity ratio" has the most relation with "operating profit" with a typical correlation coefficient 0.988 and the most relation with "net earnings"
with a typical correlation coefficient 0.966. So these firm managers should pay more attention to the labor productivity ratio.

3. Notice to the study’s results showed that among capital productivity indexes, the capital productivity ratio has the most relation with "operating profit" with a typical correlation coefficient 0.936 and the most relation with "net earnings" with a typical correlation coefficient 0.955. So those firm managers should pay more attention to the capital productivity ratio.

4. With notice to the case that through researches haven’t been done so far, it’s suggested that this study should be evaluated with methods and various instruments and in different situation and organization.

5. It’s advised that the subject of the study should be used in the private firms accepted by Tehran Stock Exchange.
